11/3 Besançon Colloquium

Dawn of Massive Quiescent Galaxies

- Everything bigger than MW is massive galaxies form & stop forming stars in merger
- Wants to know about quenching
- Is using JWST to probe early Galaxies
- What is JSTUC?
- Every web instrument has spectroscopic capabilities
- Finding old galaxies $z \sim 3-4.9$ with old stars
  - must have formed a long time ago
- found quenched galaxie at $z = 7.3$
- metalicity has a huge impact on this analysis but only changes stellar mass by around a factor of 2
- All modeling assumes MW IMF
  - Posterior that these galaxies hold pop-I stars
- Population grows dramatically starting @ $z = 5$
- Simulations have a hard time matching the # of massive Quiescent galaxies.
- ours on galaxie was detected as quenched but we prove we could that just was hiding SF
- Structural transformation happens after Quenching.
- Via oct 25 gal Quenching through lense

- Better spectra has been leading to improved models
- JWST field of view is too small to map cosmic webs
- PFS looks like a cool instrument
  - Can map cosmic webs w/ more efficiency than JWST
  - will hold set SPS
- Galaxies form earlier than old models predict, not in tension w/ ΛCDM
- Some gals efficient, quickly, others don't
